Summary

Optimising close, ongoing contact between mothers and newborn infants and enabling women to breastfeed/feed with breastmilk, or to use breastmilk substitutes as effectively and safely as possible, are key elements of maternity and neonatal care. They are especially important during the COVID-19 pandemic. Extensive evidence-based positive developments in policy and practice to promote and support mother-baby contact, attachment, and breastfeeding have been implemented across maternity and neonatal care in the UK and many other countries in the last 15-20 years, though such changes have not been universally implemented and barriers still exist in many settings. The coronavirus pandemic and the inevitable focus on reducing infection has disrupted many of these positive developments and adversely affected mother-baby contact and infant feeding in many contexts, augmenting existing barriers. Societal changes such as hygiene measures and social distancing, lockdown, isolation, fear, and food security challenges complicate the lives of women and families. Health service changes in the UK and other countries have included virtual contact between women and staff, increased separation of mothers and babies, restrictions on parental visiting in neonatal units, the use of masks and personal protective equipment, staff redeployment and shortages, and the interruption of Unicef UK Baby Friendly Initiative accreditation programmes. Taken together, these changes pose a risk to immediate, close and loving contact between the mother and newborn infant and with the other parent and the wider family, to the initiation and continuation of breastfeeding, and to future individual and family well-being and public health. Some reports are emerging about potential positive impacts of the restrictions on postnatal visiting and increased levels of virtual contact for some families in some countries.

In the context of the COVID-19 pandemic and the need to prevent or reduce infection, this rapid analytic review considers:

- What is the evidence base and best practice on optimising mother-baby contact?
- What is the evidence base and best practice on optimising infant feeding?
- What are the implications of this knowledge for guidance for health professionals, the care of women and babies, and information for women and families?

Summary of key findings and recommendations

1. While the possibility of vertical transmission cannot be completely ruled out, at the time of writing (24th June 2020) there is no conclusive evidence of in utero transmission, and there are no conclusive reports of transmission of coronavirus in breastmilk. It is essential to continue to keep this situation under review.
2. To minimise infection risk, all parents and carers should be encouraged to observe strict hygiene measures.
3. Suspected or confirmed COVID-19 positive infants and infants who have been in contact with suspected or confirmed COVID-19 positive mothers, but who are otherwise well, should not be cared for in neonatal units where the risk of infecting caregivers and immune compromised infants is high.
4. Minimising the number of caregivers the infant is exposed to is essential to reduce the infection risk both for the infant and for the caregivers.
5. Special attention is needed for women in BAME groups.
6. Separating mothers and babies is an intervention with serious consequences and it should be avoided unless essential.
7. There are no grounds for separating asymptomatic, healthy mothers and newborn infants.
8. The establishment of close and loving relationships and avoiding unnecessary separation of mother and baby is likely to help to protect against the anxiety, fear, and other mental health challenges of lockdown and the pandemic.
9. Parents who are asymptomatic should not be required to wear masks when interacting with their baby.
10. Mothers with suspected or confirmed COVID-19 should be supported and enabled to remain together with their infants when the mother is well enough, and to practice skin-to-skin/kangaroo care.
11. Unless one of the parents has suspected/confirmed COVID-19 both parents should be able to be present in the neonatal unit at all times, and should be viewed as partners in care, not visitors, and opportunities for kangaroo care should be maximised.
12. For a mother who has suspected or confirmed COVID-19 and whose baby needs to be cared for on the neonatal unit, a precautionary approach should be adopted to minimise any risk of mother-to-infant transmission; while at the same time, taking steps to involve parents in decisions and to mitigate potential problems for the baby’s health and well-being and for breastfeeding and attachment.
13. Detailed guidelines for staff and services on infant feeding in the current context should be implemented and consistently used to optimise care and to avoid inconsistent and inaccurate information for women.
14. Regardless of infant feeding method, all women need ongoing close contact with their babies and information and support with feeding until they are confident and the infant is feeding effectively.
15. Appropriate postnatal contacts and referral systems should be in place for all women and infants.
16. It is important to seek the views of women and staff about effective, context-specific ways of enabling women to breastfeed, to maximise the use of breast milk, and to minimise the risks of Breastmilk substitutes in this current crisis.
17. Breastfeeding is strongly recommended for all women and newborn infants.
18. The unique value of breastfeeding to newborn infants, women, and public health especially in this pandemic should be recognised and highlighted by health professionals, policy makers, and the public.
19. Information and support, psychological and practical, should be available to all women in pregnancy and from the first feed onwards to enable them to initiate and continue breastfeeding, including breastmilk expression.
20. Sensitive conversations about infant feeding should be conducted with all women, and should include information, encouragement and support to consider breastfeeding.
21. Women and babies should be enabled to stay together, to have skin-to-skin contact, and to breastfeed responsively.
22. If mother’s own milk is not available or where it needs supplementation, donor human milk is the option of choice, especially for vulnerable infants.
23. Women who have suspected, probable or confirmed COVID-19 should be enabled and supported to breastfeed.

24. When a woman is not well enough to care for her own infant or where direct breastfeeding is not possible, she should be supported to express her breastmilk by hand expression or by pump, and/or be offered access to donor breast milk. All feeding equipment and pumps should be appropriately cleaned and sterilised before use.

25. Accessible resources for women will be needed to inform and enable them to breastfeed, especially those from communities where breastfeeding rates are normally low and where effective interventions will be needed to enable them to start and to continue to breastfeed.

26. Parents who formula feed need information and support to enable them to bottle feed responsively and effectively.

27. Health professionals should be alert to any local problems with food security and the supply of infant formula, bottles and teats, and sterilising equipment.

28. Supporting families to claim their Healthy Start vouchers will help them to overcome some of the logistical challenges and purchase adequate supplies of formula and to access Healthy Start vitamins.

29. Accessible resources for staff will be needed to enable them to inform and support women and to have appropriately sensitive conversations with women.

30. All staff working in maternity and neonatal care need support.

31. As the current crisis abates strategies will be needed to ensure that previous evidence based services that have been put on hold or amended are not lost, but instead are reinstated and developed further, based on the best possible evidence.
Background and context

The importance of mother-baby contact and breastfeeding

Optimising close, ongoing contact between mothers and newborn infants and enabling women to breastfeed/feed with breastmilk or to use breastmilk substitutes as effectively and safely as possible, are key elements of maternity and neonatal care. There is a wealth of existing evidence that mother-baby contact and breastfeeding both have an important positive impact on short, medium, and long-term outcomes for both women and newborn infants, including mortality, health, wellbeing, attachment, and development outcomes (Acta Pediatrica, 2015; Rollins et al., 2016; Victora et al., 2016). They contribute to close mother-baby and family relationships that lay a foundation for the survival, health and wellbeing of the baby into childhood and adult life (Schore, 2001; Shonkoff et al., 2012; McManus and Nugent, 2014; National Institute for Health and Clinical Excellence, 2017; Clark et al., 2020; UNICEF, 2020).

Skin-to-skin contact, both immediate and ongoing, has physiological as well as psychological benefits for all newborn infants (Moore et al., 2016). For preterm, small, and sick newborn infants, kangaroo care is associated with reduced mortality as well as improved health outcomes (Conde-Agudelo and Díaz-Rossello, 2016).

Breastfeeding/feeding with breastmilk improves short, medium and long-term outcomes for both infants and women, and the World Health Organisation and UNICEF recommend exclusive breastfeeding for six months and thereafter with other foods for two years and beyond (https://www.who.int/nutrition/topics/global-breastfeeding-collective/en/).

Breastfeeding/feeding with breastmilk optimises the immune system, confers active and passive immunity, and protects against infection (Bode et al., 2014; Gomez-Gallego et al., 2016; Victora et al., 2016). This includes protection against life-threatening conditions for preterm, small and sick infants including necrotising enterocolitis, sepsis, and pneumonia (Cacho, Parker and Neu, 2017; Lewis et al., 2017; Woodman, 2017). Infant feeding rates are strongly socio-economically patterned. Women and newborn infants from population groups already likely to be more vulnerable to coronavirus are least likely to breastfeed, contributing to the cycle of nutritional deprivation (Dykes and Hall Moran, 2006; McAndrew et al., 2012; National Institute for Health and Clinical Excellence, 2014).

Existing practice developments and challenges

Extensive evidence-based positive developments in policy and practice to promote and support mother-baby contact, attachment, and breastfeeding have been implemented across maternity and neonatal care in the UK and many other countries in the last 15-20 years, though such changes have not been universally implemented and barriers still exist in many settings (Davies, 2013, 2015; Leadsom et al., 2013; Public Health England and Unicef UK Baby Friendly Initiative, 2016). These include immediate, uninterrupted, and ongoing skin-to-skin contact at birth, early initiation of breastfeeding, and supporting close and loving relationships for all women and newborn infants. For babies in neonatal units and their families, positive developments that are being implemented, though again not universally, include family-centred care, kangaroo care, maximising breastmilk intake, and parents as
partners in care with unrestricted access to their babies (Yu and Zhang, 2019). Multidisciplinary staff education and training in infant feeding remains a challenge however, and women and newborn infants do not reliably receive consistent care and support (Schmied et al., 2011; McAndrew et al., 2012; Yang et al., 2018). Unicef UK Baby Friendly Initiative (BFI) standards for maternity and neonatal services, health visiting services, early years settings, neonatal units, and university pre-registration midwifery and health visiting programmes have been key in promoting evidence-based practice (Entwistle, 2013; Unicef UK Baby Friendly Initiative, 2019), as have national maternity and neonatal policies in all four UK countries (Department for Health, Social Services, 2013; NHS England, 2016; The Scottish Government, 2017; Department of Health and Social Services, 2019; Welsh Government, 2019). All babies in Scotland and Northern Ireland are now born in a BFI-accredited environment, whereas in England this is only 52% (Unicef UK Baby Friendly Initiative, 2020a). In 2019, NHS England published their Long Term Plan (NHS England, 2019) which recommends that all maternity and neonatal services implement BFI accreditation, highlighting that breastfeeding rates compare unfavourably with other countries in Europe, with substantial variation across England: 84% of children reported as breastfed at 6-8 weeks in London compared to 32% in the North East.

Changes resulting from the current pandemic

The coronavirus pandemic and the inevitable focus on reducing infection has disrupted many of these developments across the UK and other countries and has adversely affected mother-baby contact and infant feeding, augmenting the barriers that still exist (Unicef UK Baby Friendly Initiative, 2020b). Mother-baby contact has been reported as being reduced or stopped in some contexts (Baker, 2020; Brown, 2020; Vogel, 2020). Forty percent of UK infant feeding services in a recent (unpublished) survey reported that their staffing has reduced as a result of the COVID-19 pandemic, and 30% report that parental access to the neonatal unit is now ‘very restricted’ (Unicef UK Baby Friendly Initiative, 2020b). This affects women and newborn infants whether in the community or hospital, whether infected with coronavirus or not, whether the newborn infant requires care in the neonatal unit or not, and at every stage of the continuum, in pregnancy, birth, and after birth. Health service changes have included reducing contact between mothers and babies, service re-design including virtual contact, use of masks and personal protective equipment (PPE), staff redeployment and shortages (Royal College of Midwives, 2020b) and the interruption of BFI accreditation programmes (Unicef UK Baby Friendly Initiative, 2020a). Societal changes including hygiene measures and social distancing, lockdown, isolation, and financial and food security challenges further complicate the lives of women and families. Taken together, they pose a risk to immediate, close and loving contact between the mother and newborn infant and with the other parent and the wider family, to the initiation and continuation of breastfeeding, and to future individual and family well-being and public health.

Some anecdotal reports are emerging about potential positive impacts of the restrictions on postnatal visiting (https://www.mumsnet.com/Talk/breast_and_bottle_feeding/3910633-Impact-of-lockdown-on-infant-feeding). Some women, their partners, and newborns are reported as having more uninterrupted time together, which may be of benefit to women in supportive home situations.
At the time of writing (24th June 2020) the available data on the potential for in-utero transmission of COVID-19 are reassuring, though it cannot be ruled out. There are no conclusive reports of transmission in breastmilk. Existing data are considered in this review.

**Review questions and aims**

In the context of the coronavirus pandemic and the need to reduce infection:

- What is the evidence base and best practice on optimising mother-baby contact?
- What is the evidence base and best practice on optimising infant feeding?
- What are the implications of this knowledge for a) guidance for health professionals, b) care of women and babies, c) information for women and families?

For each of these questions, this review will consider:

- clinical, psychological, social, and cultural aspects of safety
- the specific needs of:
  - healthy women and babies
  - women with suspected/actual SARS-CoV-2 infection
  - babies needing care in neonatal units (preterm, small, sick) and their parents

These overarching questions require consideration of related issues including:

- Optimising maternal and newborn outcomes
- Reducing/preventing infection for women, newborn infants, families, staff
- Maintaining essential aspects of quality in a time of health service, social, and economic turbulence
- Maximising workforce capacity and capability
- Optimising staff health and wellbeing
- Identifying novel or additional forms of care delivery or modifications in care

**Core principles for quality care of women and newborn infants in a pandemic**

A set of core principles for quality care of women and newborns in a pandemic have been developed to inform the series of rapid evidence review to inform RCM/RCOG, RCPCH and related guidance. They draw on evidence of essential components of quality care for all women and newborn infants (Renfrew et al., 2014) and incorporating the latest information from the World Health Organisation (World Health Organisation, 2020e, 2020b), the International Confederation of Midwives (International Confederation of Midwives, 2020b, 2020a) and the Royal College of Midwives and the Royal College of Obstetricians and
Gynaecologists on COVID-19 (Royal College of Midwives and Royal College of Obstetricians and Gynaecologists, 2020):

- Continue to provide evidence-informed, equitable, safe, respectful, and compassionate care for physical and mental health of all women and newborn infants, wherever and whenever care takes place
- Protect the human rights of women and newborn infants
- Ensure strict hygiene measures, and social distancing when possible
- Maintain community services and continuity if possible
- Ensure birth companionship by the women’s own chosen companion (who should be free of COVID-19 symptoms)
- Prevent unnecessary interventions
- Enable close contact between mother and newborn infant from birth
- Promote, enable, and value breastfeeding/breastmilk feeding and support women to breastfeed
- Involve women, families, and staff in co-designing and implementing changes
- Monitor the impact of changes including assessment of unanticipated consequences
- Protect and support maternity and neonatal staff and students, including their mental health needs

Specific additional principles related to mother-baby contact and infant feeding in a pandemic for all maternity and newborn services draw on the evidence identified in this review, World Health Organisation recommendations (World Health Organisation, 2020a) and the work of the Unicef UK Baby Friendly Initiative (Unicef UK Baby Friendly Initiative, 2020b):

- Provide information and support for all women to optimise contact with their baby, and infant feeding
- Minimise the risks of using breastmilk substitutes especially at this time of heightened risk
- Involve parents as partners in care and promote attachment and close and loving family relationships

Methods

This was a rapid review. Timing precluded a full systematic approach. A structured and transparent approach was used.

Our searches were supported by resources collated by Unicef UK Baby Friendly Initiative the British Association of Perinatal Medicine, and the Human Milk Foundation. Specific searches conducted by MIDIRS used the following databases: Maternity and Infant Care, Pubmed, The Cochrane Library, NICE and the Pan American Health Organization (PAHO) ‘COVID-19 guidance and the latest research in the Americas’. Key words used are shown in the Appendix. The last date of the structured searches was 26th May 2020; informal updates continued until 23rd June 2020.
Key findings and recommendations

Relevant studies, reviews, comments and guidelines are shown in Table 1.

Infection risk

1. While the possibility of vertical transmission cannot be completely ruled out, at the time of writing (24th June 2020) there is no conclusive evidence of in utero transmission, and there are no conclusive reports of transmission of coronavirus in breastmilk. It is essential to continue to keep this situation under review. A systematic review of 49 studies including 666 newborn infants and 655 women (K.F. Walker et al., 2020) concluded ‘Neonatal COVID-19 infection is uncommon, almost never symptomatic, and the rate of infection is no greater when the baby is born vaginally, breastfed or allowed contact with the mother’. This is confirmed by a Scientific Brief from the World Health Organisation (World Health Organisation, 2020a). Larger cohorts are needed for adequate investigation. Further work is required on the reliability of amniotic testing for the virus, and for the significance of virus specific antibodies in neonatal blood and breastmilk.

2. The newborn infant may become infected after birth. COVID-19 appears to be a fairly minor illness in young infants and may be asymptomatic (Knight et al., 2020; Zeng et al., 2020; Royal College of Paediatrics and Child Health, 2020). To minimise infection risk, all parents and carers should be encouraged to observe strict hygiene measures, including hand washing with soap and water before and after contact with their baby, and washing surfaces around the home regularly with soap and water. Women with suspected or confirmed COVID-19 should practice respiratory hygiene and wear a mask when handling the baby. (World Health Organisation, 2020b). If a fluid-resistant surgical face mask is available, this should be considered while feeding and caring for the baby (Royal College of Obstetricians and Gynaecologists, 2020)

3. Suspected or confirmed COVID-19 positive infants and infants who have been in contact with suspected or confirmed COVID-19 positive mothers, but who are otherwise well, should not be cared for in neonatal units where the risk of infecting caregivers and immune compromised infants is high. Infected infants will be potentially infectious and there are concerns that illness could potentially be more severe in preterm or otherwise immune compromised babies (Zeng et al., 2020; Royal College of Paediatrics and Child Health, 2020). They should be kept with their mothers in situations where women can practice effective hygiene measures and self-isolation; at home if the mother is well enough, or in a side ward.

4. Minimising the number of caregivers the infant is exposed to is essential to reduce the infection risk both for the infant and for the caregivers (Stuebe, 2020). Keeping newborn infants with their mothers is key to this.

5. Evidence is emerging that the BAME population is more susceptible to COVID-19 (Kirby, 2020; Knight et al., 2020). There are increased rates of mortality in women and babies from these groups, and special attention is needed for women in
BAME groups in regard to promoting contact and enabling women to breastfeed, as well as being vigilant about preventing infection and taking pro-active measures to avoid all forms of discrimination.

Mother-baby contact

6. Separating mothers and babies is an intervention with serious consequences and it should be avoided unless essential (Stuebe, 2020; World Health Organisation, 2020b; World Health Organisation Euro, 2020). It causes physiological stress in the baby (Morgan, Hom and Bergman, 2011; Moore et al., 2016; UNICEF, 2020) and the mother (Strathearn et al., 2012) and may make the infant more vulnerable to severe respiratory infections, including SARS-CoV-2, in the first year of life (Galton Bachrach, Schwarz and Bachrach, 2003; Davanzo et al., 2020).

7. There are no grounds for separating asymptomatic, healthy mothers and newborn infants. Immediate and uninterrupted contact should be encouraged, including skin-to-skin/kangaroo care, and women and newborn infants should be kept together thereafter (Scottish Government, 2020; World Health Organisation, 2020b, 2020a; World Health Organisation Euro, 2020).

8. The establishment of close and loving relationships and avoiding unnecessary separation of mother and baby is likely to help to protect against the anxiety, fear, and other mental health challenges resulting from the pandemic, lockdown, isolation, and other constraints (Charpak et al., 2017).

9. Visual face-to-face interaction with parents is important for newborn brain development and attachment (Simion et al., 2011). Parents who are asymptomatic should not be required to wear masks when interacting with their baby. If women have suspected or confirmed COVID-19, they should wear a mask when handling the baby (Royal College of Midwives and Royal College of Obstetricians and Gynaecologists, 2020; World Health Organisation, 2020e) but should be enabled to remove it and interact visually with the baby at a safe distance - ensuring that staff also remain at a safe distance - to avoid transfer of the virus by droplets (World Health Organisation, 2020d).

10. Mothers with suspected or confirmed COVID-19 should be supported and enabled to remain together with their infants when the mother is well enough, and to practice skin-to-skin/kangaroo care (World Health Organisation, 2020c). They should be cared for as an isolated dyad, in a side ward or at home, where the mother can practice effective hygiene measures as outlined in Recommendation 2. Where at all possible the mother should be the main care giver. National guidelines for infection control should be followed where medical assistance is required with use of appropriate PPE and hygiene measures.

11. Infants in neonatal units and in transitional care need contact with and care by their parents. Unless one of the parents has suspected/confirmed COVID-19 both parents should be able to be present in the neonatal unit at all times, and should be viewed as partners in care, not visitors, and opportunities for
kangaroo care should be maximised (Royal College of Paediatrics and Child Health, 2020). Neonatal units should pro-actively encourage and involve parents in the care of their baby/babies and identify ways of supporting and enabling this at all times through day and night.

12. Rarely, mothers with suspected/confirmed COVID-19 have a baby who requires care in the neonatal unit (Knight et al 2020). Considering the paucity of evidence to inform shared decisions in this situation, and acknowledging the possibility that infants requiring care in a neonatal unit (typically because of respiratory and other problems related to preterm birth, congenital anomalies, or encephalopathy) have a higher risk of severe disease due to postnatal SARS-Cov-2 infection: for a mother who has suspected or confirmed COVID-19 and whose baby needs to be cared for on the neonatal unit, a precautionary approach should be adopted to minimise any risk of mother-to-infant transmission; while at the same time, taking steps to involve parents in decisions and to mitigate potential problems for the baby’s health and well-being and for breastfeeding and attachment (Conde-Agudelo and Díaz-Rossello, 2016; Arnaez et al., 2020; Breindahl et al., 2020; Royal College of Paediatrics and Child Health, 2020; Stuebe, 2020; World Health Organisation, 2020b).
   a. Testing should be available for parents with suspected COVID-19 to avoid unnecessary separation.
   b. Infants will need to be isolated, with staff using personal protective equipment (enhanced for infants needing respiratory support that generates aerosols), at least until the RT-PCR test for SARS-CoV-2 the baby’s nasopharyngeal secretions (obtained at about 72 hours) is confirmed to be negative.
   c. Mothers with suspected/confirmed COVID-19 should be advised not to visit their infant until seven days post symptoms (or confirmed RT-PCR negative for SARS-CoV-2). It is likely that the other parent will need to self-isolate for 14 days because of contact with the baby’s mother.
   d. These decisions should be discussed with the parents whenever possible, and parents should be reassured that they remain partners in on-going decisions about their baby’s care.
   e. The mother should be offered additional support for breastmilk expression (see Recommendation 24), aligned to efforts to maximise attachment with both parents including photographs and webcam links.
   f. The baby should be reunited with the parents as soon as possible. This could include being cared for together in a side ward in a low dependency setting; where parents and staff should practice respiratory and hand hygiene, complying with current infection control advice.
   g. When discharged home, the parents should receive information and additional care as needed to promote attachment and breastfeeding.

Infant feeding

13. Detailed guidelines for staff and services on infant feeding in the current context should be implemented and consistently used to optimise care and to avoid inconsistent and inaccurate information for women. Appropriate
guidelines developed by the Scottish Government are listed in the Resources section (Scottish Government, 2020).

14. **Regardless of infant feeding method, all women need ongoing close contact with their babies, and information and support with feeding until they are confident and the infant is feeding effectively** (McFadden *et al.*, 2017). This information and support can be provided by health professionals, peer supporters, and by appropriately trained voluntary services, and be by face-to-face or virtual contact. Information is provided in the Resources section.

15. **Appropriate postnatal contacts and referral systems should be in place for all women and infants**, whether face to face or by virtual technology, and whether delivered by midwives, health visitors or the voluntary sector, to meet women's needs for information and support and address their concerns about infant feeding, until effective infant feeding is established (Scottish Government, 2020). PPE should be available for staff and volunteers conducting face to face visits. Where possible, the first visit at home (day 1 following birth or discharge home) should be prioritised as a face-to-face visit and a minimum of three visits in the first 10 days is recommended (Royal College of Midwives and Royal College of Obstetricians and Gynaecologists, 2020).

16. **It is important to seek the views of women and staff** about effective, context-specific ways of enabling women to breastfeed, to maximise the use of breast milk, and to minimise the risks of breastmilk substitutes in this current crisis (Renfrew *et al.*, 2008; McAndrew *et al.*, 2012; The Food Foundation, 2020). Information is provided in the Resources section.

**Breastfeeding and feeding with breastmilk**

17. **Breastfeeding is strongly recommended for all women and newborn infants** because of its known lifelong importance for women's and children's health and well-being (World Health Organisation, 2020b; World Health Organisation Euro, 2020). Human milk contains numerous live constituents, including immunoglobulins, antiviral factors, cytokines and leucocytes that help to destroy harmful pathogens and boost the infant's immune system (World Health Organisation Euro, 2020).

18. **The unique value of breastfeeding to newborn infants, women, and public health especially in this pandemic should be recognised and highlighted by health professionals, policy makers, and the public.** The active and passive immunity to infections conferred by breastfeeding increase its benefit even further at this time. There are growing indications that breastmilk may be a valuable source of antibodies against SARS-CoV-2 (Fox *et al.*, 2020a).

19. **Information and support, psychological and practical, should be available to all women in pregnancy and from the first feed onwards** to enable them to initiate and continue breastfeeding, including breastmilk expression; whether or not they or their infants and young children have suspected or confirmed COVID-19 (Balogun *et al.*, 2020).

20. **Sensitive conversations about infant feeding should be conducted with all women, and should include information, encouragement and support to consider breastfeeding** (Scottish Government, 2020; Unicef UK Baby Friendly Initiative, 2020b; World Health Organisation, 2020b; World Health Organisation Euro, 2020).

21. **Women and babies should be enabled to stay together, to have skin-to-skin contact, and to breastfeed responsively** to optimise the establishment of breastfeeding (Moore et al., 2016; Unicef UK Baby Friendly Initiative, 2020b).

22. Mother’s own milk should always be the first choice as this is responsive to her and her baby’s environment. However, **if mother’s own milk is not available or where it needs supplementation, donor human milk is the option of choice, especially for vulnerable infants** (World Health Organisation, 2019; Shenker, Aprigio, *et al.*, 2020). There remains no evidence to date that vertical transmission occurs through human milk (World Health Organisation, 2020a). Milk banks have adopted measures that mitigate the theoretical risk of transmission through donated milk and containers. These measures include specific questions during donor screening of SARS-CoV-2 infection or exposure, care to ensure social distancing and safety during transportation, and quarantining of milk where possible after collection (Shenker, Hughes, *et al.*, 2020). The heat instability of the virus means that it is destroyed by temperatures within the range of standard pasteurisation techniques (Rodríguez-Camejo *et al.*, 2018; Chambers *et al.*, 2020; Chin *et al.*, 2020; Conzelmann *et al.*, 2020; G.J. Walker *et al.*, 2020).

23. **Women who have suspected, probable or confirmed COVID-19 should be enabled and supported to breastfeed**, and to practice respiratory and hand hygiene when caring for and feeding their infant (Royal College of Paediatrics and Child Health, 2020; World Health Organisation, 2020c, 2020b).

24. **When a woman is not well enough to care for her own infant or where direct breastfeeding is not possible, she should be supported to express her breastmilk by hand expression or by pump, and/or be offered access to donor breast milk.**
   a. **All feeding equipment and pumps should be appropriately cleaned and sterilised before use.** Women should have a dedicated breast pump whenever possible. Methods of sterilisation that use heat, as per manufacturers guidelines, should be used to avoid where possible risk of feed contamination from chemical disinfection (Chin *et al.*, 2020; Human Milk Banking Association of North America, 2020b).

25. **Accessible resources for women will be needed to inform and enable them to breastfeed, especially those from communities where breastfeeding rates are normally low, and where effective interventions will be needed to enable them to start and to continue to breastfeed** (Renfrew *et al.*, 2008; Balogun *et al.*, 2016;
McFadden et al., 2017; Relton et al., 2018). Appropriate links are listed below in the Resources section.

Formula feeding

26. **Parents who formula feed need information and support to enable them to bottle feed responsibly and effectively**, including pacing feeds and limiting the number of people who feed their baby. They should be encouraged to adhere to current guidance on washing and sterilising equipment. Appropriate resources developed by Unicef UK Baby Friendly Initiative are listed in the Resources section (Scottish Government, 2020; Unicef UK Baby Friendly Initiative, 2020b; Unicef UK Baby Friendly Initiative, First Steps Nutrition and National Infant Feeding Network, 2020).

27. **Health professionals should be alert to any local problems with food security** and the supply of infant formula, bottles and teats, and sterilising equipment. Women may need support to find appropriate suppliers, or to re-lactate (Unicef UK Baby Friendly Initiative, 2020b; Unicef UK Baby Friendly Initiative, First Steps Nutrition and National Infant Feeding Network, 2020). Midwives should be aware of the impact of food poverty (Etheridge, 2014; The Food Foundation, 2019, 2020; Pérez-Escamilla, Cunningham and Moran, 2020), which is likely to increase in the wake of the pandemic.

28. Increasing numbers of families rely on universal credit at this time of social and economic turbulence, and existing inequities are likely to be exacerbated by this pandemic. Families in receipt of universal credit are entitled to Healthy Start vouchers or the equivalent in devolved nations. **Supporting families to claim their Healthy Start vouchers will help them to overcome some of the logistical challenges and purchase adequate supplies of formula and to access Healthy Start vitamins** (McFadden et al., 2014, 2015; Ohly et al., 2017; Unicef UK Baby Friendly Initiative, First Steps Nutrition and National Infant Feeding Network, 2020).

Staff

29. **Accessible resources for staff will be needed to enable them to inform and support women and to have appropriately sensitive conversations with women** ([https://www.unicef.org.uk/babyfriendly/guidance-documents/](https://www.unicef.org.uk/babyfriendly/guidance-documents/)). Staff shortages and redeployment mean that not all staff caring for women in pregnancy, at birth, and postnatally will be up to date with the knowledge and skills to help women with breastfeeding (Unicef UK Baby Friendly Initiative, 2020b), and they may need easily accessible support so they can rapidly learn to do this effectively and sensitively. Appropriate resources to support staff in this situation, developed by Unicef UK BFI, are listed in the Resources section.

30. **All staff working in maternity and neonatal care need support.** The pandemic and its impact on health services and the care of women and newborn infants is stressful for staff as well as for parents (Hunter, Renfrew and Downe, 2020; Renfrew et al., 2020a). Staff shortages, long shifts, and anxiety about COVID-19 are common...
(Royal College of Midwives, 2020a). Staff who have been working to implement improvements in care, including family-centred care, skin-to-skin and kangaroo care, and the Unicef UK BFI standards, and to enable and support women with breastfeeding, may experience additional stress including moral distress, as their work seems to be stopped or even reversed (Arnaez et al., 2020; Greenberg et al., 2020).

31. **As the current crisis abates strategies will be needed to ensure that previous evidence based services that have been put on hold or amended are not lost, but instead are reinstated and developed further, based on the best possible evidence.** Interdisciplinary team working and the involvement of women and families in service re-design will be essential to continue the development of quality maternity and neonatal care (Arnaez et al., 2020; Renfrew et al., 2020b).
Resources for staff and parents

Staff:

- COVID-19 relevant, evidence-based guidance sheets for staff have been developed by Unicef UK BFI and are available at [https://www.unicef.org.uk/babyfriendly/guidance-documents/](https://www.unicef.org.uk/babyfriendly/guidance-documents/)

- Unicef UK Baby Friendly Initiative easy-to-use education refresher sheets for staff working to deliver postnatal care during the coronavirus outbreak [https://www.unicef.org.uk/babyfriendly/education-refresher-sheets/](https://www.unicef.org.uk/babyfriendly/education-refresher-sheets/)

- Unicef UK Baby Friendly Initiative resources on maximising breastmilk [https://www.unicef.org.uk/babyfriendly/baby-friendly-resources/breastfeeding-resources/maximising-breastmilk/](https://www.unicef.org.uk/babyfriendly/baby-friendly-resources/breastfeeding-resources/maximising-breastmilk/)

- Information on infant formula and bottle feeding from Unicef UK Baby Friendly Initiative: [https://www.unicef.org.uk/babyfriendly/baby-friendly-resources/bottle-feeding-resources/](https://www.unicef.org.uk/babyfriendly/baby-friendly-resources/bottle-feeding-resources/)

Parents:

- Appropriate resources for parents:

- The National Breastfeeding Helpline is available 7 days a week, from 9.30am to 9.30pm: [https://www.breastfeedingnetwork.org.uk/coronavirus/](https://www.breastfeedingnetwork.org.uk/coronavirus/)

- Breastfeeding support can be accessed from national voluntary organisations:
  - NCT: [https://www.nct.org.uk/](https://www.nct.org.uk/)
  - La Leche League GB: [https://www.laleche.org.uk/](https://www.laleche.org.uk/)
  - The Breastfeeding Network: [www.breastfeedingnetwork.org.uk](http://www.breastfeedingnetwork.org.uk)

<td>Coronavirus Disease 2019 (COVID-19) and Pregnancy: What obstetricians need to know</td>
<td>This editorial examines the evidence presented in Dong et al. 2020 and Zeng et al. 2020. It concludes that there is not virologic evidence for congenital infection to support the serologic suggestion of in utero transmission. 'Is it possible that SARS-CoV-2 can be transmitted in utero? Yes, especially because virus nucleic acid has been detected in blood samples. Is it also possible that these results are erroneous? Absolutely. Although these 2 studies deserve careful evaluation, more definitive evidence is needed before the provocative findings they report can be used to counsel pregnant women that their fetuses are at risk from congenital infection with SARS-CoV-2'.</td>

**Possibility of transmission via breastfeeding**

Transmission: Pregnant women are no more vulnerable than the general public, but some women may have a more severe immune response with more severe symptoms. There may be a cohort of asymptomatic individuals, with minor symptoms, incidence is unknown. Vertical transmission is possible but no evidence for this yet. No evidence that the virus is teratogenic. The newborn may become infected after birth. The benefits of breastfeeding far outweigh potential risks of virus in breast milk. Breastfeeding should be promoted and supported. An increase in levels of anxiety is to be expected. Acknowledge anxieties and build awareness and signing into routes of support including remote access.

**Breastfeeding**

- Infants of -ve SARS-CoV-2 admitted to NNU do not need to isolated.
- If mother or infant has any respiratory pathology both should be tested.
- Parents should be treated as part of therapeutic team.
- Neonatal units should involve parents and identify how to support this at all times of the day 24/7.
- Skin to skin and breastfeeding supported and enabled.
- Both parents to be able to be present, should not be viewed as visitors.
- Testing should be available to enable parents to stay with their baby.
- Mothers should be supported to have skin to skin in the nursery unless suspected or confirmed +ve.
- +ve parents should not be present on the NNU until 7 days after the onset of the illness.
- EBM hand hygiene, safe transport and storage as per EMBA position statement.
- Mothers should have designated breast pump.

Hygiene measures to prevent infection while breastfeeding.

</tr>
<tr>
<td>Bullard et al. 22/05/20 Canada</td>
<td>(Bullard et al., 2020)</td>
<td>Clinical Infectious Diseases</td>
<td>Original research</td>
<td>Performed cell culture on 90 nasopharyngeal or endotracheal clinical samples. Found no infectivity with Ct values &gt;24 and samples more than 8 days after symptom onset. Lower Ct values confer greater infectivity. All milk samples recorded as ‘positive’ to date have had Ct values over 30, showing it took more rounds of PCR amplification to record a positive result. This paper suggests that would be too few viral particles to infect infants during feeding. It might also represent fragments of virus that are antigenic in the infant to generate an immune response, which would potentially be protective.</td>

(coronavirus OR COVID-19 OR covid-19) AND (breastfeed* OR “breast feed* OR “bottle feed* OR “infant feeding” OR “infant formula") AND (coronavirus OR COVID-19 OR covid-19) AND (breastfeed* OR “breast feed*” OR “bottle feed* OR “bottle-feed* OR “infant feed* OR “infant-feed*)

Infant feeding in emergency situations

Keywords

Example search strings
(breastfeed* OR “breast feed*” OR breast-feed* OR “bottle feed* OR “infant feeding” OR “infant formula") AND (emergenc* OR war* OR disaster* OR earthquake* OR hurricane* OR tsunami* OR famine)
(“donor milk” OR “donor breast milk”) AND (emergenc* OR war* OR disaster* OR earthquake* OR hurricane* OR tsunami* OR famine)
Search pack PN3 – Breastfeeding the baby in intensive care
PN3 – Breastfeeding the baby in intensive care, is one of over 600 search packs compiled and regularly updated by MIDIRS Librarians when selecting items for the Maternity and Infant Care (MIC) database. Each search pack comprises collections of records on a particular topic, selected from a wide range of information resources that include more than 400 journals and other research materials.
